The Scala Type System

Scala Quick Ref @ Lund University

Pull requests welcome! Contact: bjorn.regnell@cs.lth.se License: CC-BY-SA, © Dept. of Computer Science, Lund University. https://github.com/lunduniversity/introprog/tree/master/quickref

Zop-level definitions

Compile: scalac hello.scala supile: scalac hello.scala supile supile blnoWolleH.z.y.x	{
A compilation unit (here hello.scala) consists of a sequence of packagings, import clauses, and class and object definitions, which may be preceded by a package clause, e.g.: package x.y.z that places the compiled file HelloWorld.class in directory x/y/z/	<pre>// in file: hello.scala package x.y.z object HelloWorld { def main(args: Array[String]): Unit = { println("Hello World")</pre>

Definitions and declarations

Variable val x = expr

Object

abstract member. Below defsAndDecl denotes a list of definitions and/or declarations. Modifiers on next page. A definition binds a name to a value/implementation, while a declaration just introduces a name (and type) of an

The Scala Standard Collection Library

Concrete implementations of Map include HashMap and ListMap. The subtype SortedMap is implemented by TreeMap. Concrete implementations of Set include HashSet, ListSet and BitSet. The subtype SortedSet is implemented by TreeSet.

```
class A(initX: Int = 0) {
                                                primary constructor: new A(1) or using default arg: new A()
                                               private member only visible in A and its companion
  private var _x = initX
                                               getter for private field x (name chosen to avoid clash with x)
  def x: Int = _x
  def x_{-}=(i: Int): Unit = \{ x = i \} special setter assignment syntax: val a = new A(1); a.x = 2
object A {
                                               companion object if same name and in same code file
  def apply(init: Int = 0): A = new A(init) factory method, new not needed: A.apply(1), A(1), A()
                                               Private members can be accessed in companion
  val a = A(1).x
Getters and setters above are auto-created by using var in primary constructor: class A(var x: Int = 0)
Enforce the use of factory in companion only by private constructor: class A private (var x: Int = 0)
Instead of default arguments, an auxiliary constructor can be defined (less common): def this() = this(0)
```

Expressions

literals block if match for yield while do while throw	<pre>0 0L 0.0 "0" '0' true false { expr1;; exprN } if (cond) expr1 else expr2 expr match caseClauses for (x <- xs) expr for (x <- xs) yield expr while (cond) expr do expr while (cond) throw new Exception("Bang!") try expr catch pf</pre>	Basic types e.g. Int, Long, Double, String, Char, Boolean The value of a block is the value of its last expression Value is expr1 if cond is true, expr2 if false (else is optional) Matches expr against each case clause, see pattern matching. Loop for each x in xs, x visible in expr, type Unit Yeilds a sequence with elems of expr for each x in xs Loop expr while cond is true, type Unit Do expr at least once, then loop while cond is true, type Unit Throws an exception that halts execution if not in try catch Evaluate partial function pf if exception in expr, where pf e.g.:
try	try expr catch pf	Evaluate partial function pf if exception in expr, where pf e.g.: {case e: Exception => someBackupValue}

Precedence	of ops beginning with:	Example expressions:	Explanation, x,y of type Int
Lowest:	all letters	(x + 2) * i / 3	Parenthesis control order of evaluation
		1.+(2)	Method application, call method + on object 1
	^	1 + 2	Operator notation equivalent to 1.+(2)
	&	x < y	Yields true or false, other ops: > <= >= == !=
	= !	cond1 && cond2	Logical and; other boolean ops are or: not: !
	< >	f(1, 2, 3)	Function application, same as f.apply(1,2,3)
	:	x => x + 1	Function literal, anonymous function, "lambda"
	+ -	new C(1,2)	Create object from class C with arguments 1,2
	* / %	this	A reference to the object being defined
Highest:	other special chars	super.m	Refers to a member m of a supertype of this
Exception:	assignment = is lowest	null	Refers to a non-referable object of type Null

TODO += -= etc

Tuples

TODO

Generic classes and methods

```
class Box[A](val a: A){
  def pairedWith[B](b: B): (A, B) = (a, b)
scala> new Box(new Box(0)).pairedWith(new Box(0.0))
res65: (Box[Int], Box[Double]) = (Box@2a7e0b92,Box@713ea923)
```

Generic types are erased before JVM runtime except for Arrays, so a reflect. ClassTag is needed when constructing arrays from type arguments: **def** mkArray[A:reflect.ClassTag](a: A) = Array[A](a)

3(8)

Scala

Pattern matching and type tests

}

```
expr match {
  case pattern1 => expr1
                                     TODO Explanation
  case patternN => exprN
  case _ =>
Option, Some, None
opt match {
  case Some(x) \Rightarrow f(x)
                                     TODO Explanation
  case None =>
scala.util.Try
                                   TODO Explanation
Try{expr1}.get0rElse(expr2)
                                   TODO Explanation
Try{expr1}.recover(expr2)
Reading/writing from file and standard in/out:
Read lines from file: (second param can be "Utf-8", fromFile gives Iterator[String], also fromURL)
val lines = scala.io.Source.fromFile("file.txt").getLines.mkString("\n")
Read string from standard in (prompt is optional) and printing to standard out:
val s: String = scala.io.StdIn.readLine("prompt"); println("you wrote" + s)
Saving string to file using java.nio and charset UTF 8:
def save(fileName: String, data: String) = {
     import java.nio.file.{Paths, Files}
     import java.nio.charset.StandardCharsets.UTF_8
```

Files.write(Paths.get(fileName), data.getBytes(UTF_8))

Strings

Scala

8(8)

Methods in trait Traversable[A]

Make string:	xs mkString (start, sep, end)	A string with all elements of xs between separators sep enclosed in strings start and end; start, sep, end are all optional.
	xsm.ex nim.ex	which must be numeric.
	xs.sum xs.product	Calculation of the sum/product/min/max of the elements of xs,
	xs reduceRight op	with first element instead of z.
	xs reduceLeft op	Similar to foldLeft/foldRight, but xs must be non-empty, starting
	(qo)(z)jhgiAbloì.ex	going left to right (or right to left) starting with z.
Folds:	. (qo)(z)tlalolosx	Apply binary operation op between successive elements of xs,
	xe conuf b	An Int with the number of elements in xs that satisfy p.
	g sisixə ex	Returns true if p holds for some element of xs.
:snoitibno	d Jianot ex	Returns true if p holds for all elements of xs.
	xs groupBy f	Partition xs into a map of collections according to f.
	xs partition p	Split xs by p into the pair (xs filter p, xs.filterNot p)
	d ueds sx	Split xs by p into the pair (xs takeWhile p, xs.dropWhile p).
	n fAfilqe ex	Split xs at n returning the pair (xs take n, xs drop n).
	a filterNot p	Those elements of xs that do not satisfy the predicate p.
	xs filter p	Those elements of xs that satisfy the predicate p.
	xs dropWhile p	Without the longest prefix of elements that all satisfy p.
	xs takeWhile p	The longest prefix of elements all satisfying p.
	xs quob n	The rest of the collection except xs take n.
	xs take n	The first n elements (or some n elements, if order undefined).
	xs slice (from, to)	The elements in from index from until (not including) to.
Subparts:	tini.ex liai.ex	The rest of the collection except xs.head or xs.last.
	q bnil ex	An option with the first element satisfying p, or None.
	noilqOlssI.ex	defined) in an option value, or None if xs is empty.
	noilq0be9d.ex	The first/last element of xs (or some element, if no order is
Retrieval:	tsal.ead xs.last	The first/last element of xs (or some elem, if order undefined).
	9ziz.ex	Returns an Int with the number of elements in xs.
	γjqm∃non.ex	Returns true if the collection xs has at least one element.
:ołni əziZ	γjqm∃si.ex	Returns true if the collection xs is empty.
_	(u 's	at index s (last two arguments are optional). Return type Unit.
	xs copyToArray (arr,	Copies at most n elements of the collection to array arr starting
сору:	xs copyToBuffer buf	Copies all elements of xs to buffer buf. Return type Unit.
	toMap	Converts a collection of key/value pairs to a map.
	19201	Converts the collection to a set; duplicates removed.
	toBuffer toArray	matches the demanded type.
:ТэупоЭ	toVector toList toSeq	Converts a collection. Unchanged if the run-time type already
	4	xs for which it is defined (undefined ignored).
	xs collect pf	The collection obtained by applying the pf to every element in
	ı dayana ev	tion) to all elements in xs and concatenating the results.
·dnu	1 qsm ex	A collection obtained by applying f (which must return a collec-
Map:	1 qsm ex	A collection formed by applying f to every element in xs.
Add:	× ++ λε	A collection with xs followed by ys.
Traverse:	xs foreach f	Executes 1 for every element of xs. Return type Unit.
JadW	egesU	Explanation f is a function, pf is a partial funct., p is a predicate.

Strings are implictly treated as Seq[Char] so all Seq methods also works. Some methods below are from Java. lang. String and some methods are implicitly added from StringOps, etc.

```
Removes leading and trailing white space.
                                                                                                mint.2
                          Converts all characters to upper case.
                                                                                       s.toUpperCase
                          Converts all characters to lower case.
                                                                                       s.toLowerCase
                                Converts a number to a String.
                                                                    42.0.toString
                                                                                        42.toString
        Parses s as an Int or Double etc. May throw an exception.
                                                                teolAot.a sitoDouble sitoFloat
                Returns a substring of s from index i to index j-1.
                                                                                  (i, i) gritring(i, j)
          Returns a substring of s with all charcters from index i.
                                                                                      s.substring(i)
 Strips leading white space followed by I from each line in string.
                                                                                       s.stripMargin
                            True if string s begins with string t.
                                                                                    s.startsWith(t)
Returns an array of strings split at every occurance of charachter c.
                                                                                           (c) tilqe.e
                       Replace all occurances of s1 with s2 in s.
                                                                 s.replaceAllLiterally(s1, s2)
                              True if string s ends with string t.
                                                                                       s.endsWith(t)
                                                                        s.compareToIgnoreCase(t)
                 Similar to compateTo but not sensitive to case.
        Returns x where x < 0 if s < t, x > 0 if s > t, x is 0 if s = t
                                                                                      s.compareTo(t)
   Returns this string with first character converted to upper case.
                                                                                        s.capitalize
                               Returns the character at index i.
                                                                 s(i) s apply i s.charAt(i)

java.util.concurrent.ConcurrentMap

Reserved words

These 40 words and 10 symbols have special meaning and cannot be used as identifiers in Scala.

type val var while with yield _ : = => package private protected return sealed super this throw trait try true forSome if implicit import lazy macro match new null object override abstract case catch class def do else extends false final finally for

Methods in trait Iterable[A]

What	Usage	Explanation
Iterators:	val it = xs.iterator	An iterator it of type Iterator that yields each element one
		<pre>by one: while (it.hasNext) f(it.next)</pre>
	xs grouped size	An iterator yielding fixed-sized chunks of this collection.
	xs sliding size	An iterator yielding a sliding fixed-sized window of elements.
Subparts:	xs takeRight n	Similar to take and drop in Traversable but takes/drops
	xs dropRight n	the last n elements (or any n elements if the order is undefined).
Zippers:	xs zip ys	An iterable of pairs of corresponding elements from xs and ys.
	xs zipAll (ys, x, y)	Similar to zip, but the shorter sequence is extended to match
		the longer one by appending elements x or y.
	xs.zipWithIndex	An iterable of pairs of elements from xs with their indices.
Compare:	xs sameElements ys	True if xs and ys contain the same elements in the same order.

Methods in trait Seq[A]

Indexing	xs(i) xs apply i	The element of xs at index i.
and size:	xs.length	Length of sequence. Same as size in Traversable.
	xs.indices	Returns a Range extending from 0 to xs.length - 1.
	xs isDefinedAt i	True if i is contained in xs.indices.
	xs lengthCompare n	Returns -1 if xs is shorter than n, +1 if it is longer, else 0.
Index	xs indexOf x	The index of the first element in xs equal to x.
search:	xs lastIndexOf x	The index of the last element in xs equal to x.
	xs indexOfSlice ys xs lastIndexOfSlice ys	The (last) index of xs such that successive elements starting from that index form the sequence ys.
	xs indexWhere p	The index of the first element in xs that satisfies p.
	xs segmentLength (p, i)	The length of the longest uninterrupted segment of elements in xs, starting with xs(i), that all satisfy the predicate p.
	xs prefixLength p	Same as xs.segmentLength(p, 0)
Add:	x +: xs xs :+ x	Prepend/Append x to xs. Colon on the collection side.
	xs padTo (len, x)	Append the value x to xs until length len is reached.
Update:	xs patch (i, ys, r)	A copy of xs with r elements of xs replaced by ys starting at i.
•	xs updated (i, x)	A copy of xs with the element at index i replaced by x.
	xs(i) = x	Only available for mutable sequences. Changes the element of
	xs.update(i, x)	xs at index i to x. Return type Unit.
Sort:	xs.sorted	A new Seq[A] sorted using implicitly available ordering of A.
	xs sortWith lt	A new Seq[A] sorted using less than lt: (A, A) => Boolean.
	xs sortBy f	A new Seq[A] sorted using implicitly available ordering of B after applying f: A => B to each element.
Reverse:	xs.reverse	A new sequence with the elements of xs in reverse order.
	xs.reverseIterator	An iterator yielding all the elements of xs in reverse order.
	xs reverseMap f	Similar to map in Traversable, but in reverse order.
Tests:	xs startsWith ys	True if xs starts with sequence ys.
	xs endsWith ys	True if xs ends with sequence ys.
	xs contains x	True if xs has an element equal to x.
	xs containsSlice ys	True if xs has a contiguous subsequence equal to ys
	(xs corresponds ys)(p)	True if corresponding elements satisfy the binary predicate p.
Subparts:	xs intersect ys	The intersection of xs and ys, preserving element order.
	xs diff ys	The difference of xs and ys, preserving element order.
	xs union ys	Same as xs ++ ys in Traversable.
_	xs.distinct	A subsequence of xs that contains no duplicated element.

Methods in trait Set[A]

xs(x) xs apply x	True if x is a member of xs. Also: xs contains x
xs subsetOf ys	True if ys is a subset of xs.
xs + x xs - x	Returns a new set including/excluding elements.
xs + (x, y, z) xs - (x, y, z)	Addition/subtraction can be applied to many arguments.
xs intersect ys	A new set with elements in both xs and ys. Also: &
xs union ys	A new set with elements in either xs or ys or both. Also:
xs diff ys	A new set with elements in xs that are not in ys. Also: &~

Additional mutation methods in trait mutable. Set[A]

xs += x xs += (x, y,	xs -= x z) xs -= (x, y, z)	Returns the same set with included/excluded elements. Addition/subtraction can be applied to many arguments.
xs ++= ys		Adds all elements in ys to set xs and returns xs itself.
xs add x		Adds element x to xs and returns true if x was in xs, else false.
xs remove x		Removes x from xs and returns true if x was in xs, else false.
xs retain p		Keeps only those elements in xs that satisfy predicate p.
xs.clear		Removes all elements from xs. Return type Unit.
xs(x) = b	xs.update(x, b)	If b is true, adds x to xs, else removes x. Return type Unit.
xs.clone		Returns a new mutable set with the same elements as xs.

Methods in trait Map[K, V]

ms get k	The value associated with key k an option, None if not found.
ms(k) xs apply k	The value associated with key k, or exception if not found.
ms getOrElse (k, d)	The value associated with key k in map ms, or d if not found.
ms isDefinedAt k	True if ms contains a mapping for key k. Also: ms.contains(k)
ms + (k -> v) $ms + ((k, v))$	The map containing all mappings of ms as well as the mapping
ms updated (k, v)	k -> v from key k to value v. Also: ms + (k -> v, l -> w)
ms - k	Excluding any mapping of key k. Also: ms - (k, l, m)
ms ++ ks ms ks	The mappings of ms with the mappings of ks added/removed.
ms.keys ms.values	An iterable containing each key/value in ms.

Additional mutation methods in trait mutable. Map[K, V]

<pre>ms(k) = v ms.update(k, v)</pre>	Adds mapping k to v, overwriting any previous mapping of k.
ms += (k -> v) $ms -= k$	Adds/Removes mappings. Also vid several arguments.
ms put (k, v) ms remove	k Adds/removes mapping; returns previous value of k as an option.
ms retain p	Keeps only mappings that have a key satisfying predicate p.
ms.clear	Removes all mappings from ms.
ms transform f	Transforms all associated values in map ms with function f.
ms.clone	Returns a new mutable map with the same mappings as ms.

Factory methods examples: Vector(0, 0, 0) same as Vector.fill(3)(0)
collection.mutable.Set.empty[Int]; Map("se" -> "Sweden", "dk" -> "Denmark")
Array.ofDim[Int](3,2) gives Array(Array(0, 0), Array(0, 0), Array(0, 0)) same as
Array.fill(3,2)(0); Vector.iterate(1.2, 3)(_ + 0.5) gives Vector(1.2, 1.7, 2.2);
Vector.tabulate(3)("s" + _) gives Vector("s0", "s1", "s2")

cond är ett logiskt uttryck. Med . . . avses valfri, extra kod. Hakparenteser [] markerar valfria delar. En sats betecknas stmt medan x, i, s, ch är variabler, exprär et uttryck, Vertikalstreck | används mellan olika alternativ. Parenteser () används för att gruppera en mängd alternativ.

Java snabbreferens @ Lunds universitet

{stmtl; stmtc; ...} tungerar "utifrån" som **en** sats

```
Uttryck
                returnerar funktionsresultat
                                                                   return expr;
                                                                                         return-sats
                     så länge cond är true
                                                               } while (cond);
                                                                 sfmt; ···
                     ıtförs minst en gång,
                                                                                      do-while-sats
                                                  while (cond) {stmt; ...}
                utförs så länge cond är true
                                                                                         while-sats
                  fungerar även med array
                                                                 ... ; tmls
             x blir ett element i taget ur xs
           xs är en samling, här med heltal
                                                            } (sx :x fni) Tof
                                                                                       for-each-sats
            i++ kan ersättas med i = i + step
                                                                 ... ; tmls
                d =< s mo gnåp nəpni sröð
          satserna gors for i = a, a+1, ..., b-1
                                           for (int i = a; i < b; i++) {
                                                                                           tor-sats
sats efter default: utförs om inget case passar
                                                default: stmtN; break;
           "faller igenom" om break saknas
           utförs om expr = A (A konstant)
                                                 case A: stmtl; break;
                  expr är ett heltalsuttryck
                                                               switch (expr) {
                                                                                        syitch-sats

Reserverade ord

Medan 50 ord kan ej användas som identifierare i Java. Orden **goto** och **const** är reserverade men används ej.

switch synchronized this throw throws transient try void volatile while package private protected public return short static strictfp super goto if implements import instanceof int interface long native new continue default do double else enum extends final finally float for abstract assert boolean break byte case catch char class const

Deklarationer

Allmänt	[<protection>] [static] [final] <type> name1, name2,;</type></protection>	
<type></type>	byte short int long float double boolean char Classname	
<pre><pre><pre><pre><pre><pre><pre><pre></pre></pre></pre></pre></pre></pre></pre></pre>	public private protected	för attribut och metoder i klasser (paketskydd om inget anges)
Startvärde	int x = 5;	startvärde bör alltid anges
Konstant	final int N = 20;	konstantnamn med stora bokstäver
Array	<type>[] vname = new <type>[10];</type></type>	deklarerar och skapar array

Klasser

```
Deklaration
                      [ public ] [ abstract ] class Classname
                          [ extends Classname1 ] [ implements Interface1, Interface2, ... ] {
                          <deklaration av attribut>
                          <deklaration av konstruktorer>
                          <deklaration av metoder>
Attribut
                     Som vanliga deklarationer. Attribut får implicita startvärden, 0, 0.0, false, null.
Konstruktor
                     conto Classname(param, ...) {
                                                            Parametrarna är de parametrar som ges vid
                                                            new Classname(...). Satserna ska ge
                         stmt; ...
                                                            attributen startvärden
Metod
                     om typen inte är void måste en return-
                                                            sats exekveras i metoden
                          stmt; ...
                     public static void main(String[] args) { ... }
Huvudprogram
Abstrakt metod
                     Som vanlig metod, men abstract före typnamnet och \{\ldots\} ersätts med semikolon. Metoden
                     måste implementeras i subklasserna.
```

Standardklasser, java.lang, behöver inte importeras

Object	Superklass till alla klasser.	
	boolean equals(Object other); int hashCode(); String toString();	ger true om objektet är lika med other ger objektets hashkod ger en läsbar representation av objektet
Math	Statiska konstanter Math.Pl och Math.E. N	Metoderna är statiska (anropas med t ex Math.round(x)):
	long round(double x); int abs(int x); double hypot(double x, double y); double sin(double x); double exp(double x); double pow(double x, double y); double log(double x); double sqrt(double x);	avrundning, även float \to int $ x $, även double, $\sqrt{x^2+y^2} \\ \sin x$, liknande: cos, tan, asin, acos, atan $e^x \\ x^y \\ \ln x \\ \sqrt{x}$
	double toRadians(double deg);	$deg \cdot \pi/180$
System	void System.out.print(String s); void System.out.println(String s); void System.exit(int status); Parametern till print och println kan var.	skriv ut strängen s som print men avsluta med ny rad avsluta exekveringen, status!= 0 om fel a av godtycklig typ: int, double,

Wrapperklasser För varje datatyp finns en wrapperklass: char \rightarrow Character, int \rightarrow Integer, double \rightarrow Double, ...

Statiska konstanter MIN VALUE och MAX VALUE ger minsta respektive största värde. Exempel

med klassen Integer:

Integer(int value); skapar ett objekt som innehåller value

tar reda på värdet int intValue():

Teckensträngar där tecknen inte kan ändras. "asdf" är ett String-objekt. s1 + s2 för att konkatenera

två strängar. StringIndexOutOfBoundsException om någon position är fel.

int length(): antalet tecken

char charAt(int i); tecknet på plats i, 0..length()-1

boolean equals(String s); jämför innehållet (s1 == s2 fungerar inte) int compareTo(String s); < 0 om mindre, = 0 om lika, > 0 om större

int indexOf(char ch); index för ch, -1 om inte finns

int indexOf(char ch, int from); som indexOf men börjar leta på plats from

String substring(int first, int last); kopia av tecknen first..last-1String[] split(String delim); ger array med "ord" (ord är följder av

tecken åtskilda med tecknen i delim)

Konvertering mellan standardtyp och String (exempel med int, liknande för andra typer):

String.valueOf(int x); $x = 1234 \rightarrow "1234"$

s = "1234" \rightarrow 1234. NumberFormat-Integer.parseInt(String s);

Exception om s innehåller felaktiga tecken

StringBuilder Modifierbara teckensträngar. length och charAt som String, plus:

> StrinaBuilder(Strina s): StringBuilder med samma innehåll som s

void setCharAt(int i. char ch): ändrar tecknet på plats i till ch

lägger till s. även andra typer: int. char. ...

StringBuilder insert(int i, String s); lägger in s med början på plats i tar bort tecknet på plats i StringBuilder deleteCharAt(int i); skapar kopia som String-objekt

Standardklasser, import java.util.Classname

List<E> är ett gränssnitt som beskriver listor med objekt av parameterklassen E. Man kan lägga in

värden av standardtyperna genom att kapsla in dem, till exempel int i Integer-objekt. Gränssnittet implementeras av klasserna ArrayList<E> och LinkedList<E>, som har samma operationer. Man ska inte använda operationerna som har en position som parameter på en LinkedList (i stället

en iterator). IndexOutOfBoundsException om någon position är fel.

För att operationerna contains, indexOf och remove(Object) ska fungera måste klassen E över-

skugga funktionen equals(Object). Integer och de andra typklasserna gör det.

ArrayList<E>(); skapar tom lista LinkedList<E>(); skapar tom lista antalet element int size();

boolean isEmpty(); ger true om listan är tom E aet(int i): tar reda på elementet på plats i int indexOf(Object obj): index för obi. -1 om inte finns boolean contains(Object obj); ger true om obj finns i listan

void add(E obj); lägger in obj sist, efter existerande element void add(int i, E obj); lägger in obj på plats i (efterföljande

element flyttas)

E set(int i, E obi); ersätter elementet på plats i med obj E remove(int i); tar bort elementet på plats i (efter-

följande element flyttas)

boolean remove(Object obj); tar bort objektet obj, om det finns void clear(); tar bort alla element i listan

String

StringBuilder append(String s):

String toString():

List

ArrayList I inkedI ist
